- Removing the item with the lowest price from the sale is an external action which has to be handled by the "Register", by Controller.

Furthermore, the "Register" delegates this responsibility to the "Sale", by Indirection, because "Sale" has the necessary information to perform this task, "Sale" contains a collection (e.g. List) of "SaleLineItems".
⇒ Information expert.

In addition, also by Information Expert, the list of "SaleLineItem" will figure out the item with the lowest price. This is done by asking the "ProductSpecification" about the price of each item. ⇒ Inform. Expert

- For computing the total amount of the Information Expert pattern is used as follows:
 - "Sale" knows how to compute the total value of the "SaleLineItem" list by summing up all subtotals.
 - "SaleLineItem" knows how to compute its subtotal by $\text{quantity} \times \text{Price}$
 - "ProductSpecification" is responsible for knowing its own price.

- Both use cases were represented on the diagram above. These designs maintain the low coupling property because they do not alter the ~~design~~ domain model by adding dependencies.

In addition, high cohesion is preserved because the added operation (removeLowestPrice) is related to the already present functionality of the class (list operations).

- In conclusion, the desired properties of low coupling and high cohesion are present in this design. No extra dependencies are created and the responsibilities implied are strongly related.
